Leveraging the Mouse The computer mouse was invented by psychologist Melvin C. Steele at the University of California, Berkeley in 1971, and was made commercially available in 1977. Steele was dissatisfied with existing solutions for drawing and drafting software, and he wanted to create a device that could be used to control the mouse pointer without having to move a finger or stylus. The problem Steele had to solve was making a device that could be used to move the mouse pointer, but not be considered an input device, such as a typewriter or a joystick. This is different from a mouse, which we use to move a pointer. Steele's mouse solved that problem by using a design that allowed the ball of the mouse to move freely over a surface in two dimensions, but also to move in the other two dimensions when the ball of the mouse was lifted off the surface. In addition, there was an internal potentiometer that told the computer where the user was on the surface, and how far the user had moved the ball. Steele thought up the idea for the mouse at the time because he was looking for a way to use his computer mouse, but it eventually was adopted by many other developers of drawing and drafting software. Mouse as a Mouse Steele's mouse helped to increase the adoption of computers for drafting and design, but it did not greatly increase the use of computers in drafting and design. One reason is that the size of the mouse ball (the knurled wheel) was too small. This meant that a user had to pick up the mouse and lift the ball to use the mouse. If the user had to move the mouse that far, then it was unlikely that the user would pick up the mouse every time he or she wanted to use the mouse. The other reason is that the mouse was not seen as an input device. When users had to lift the mouse, they were not using the mouse as a pointing device. Also, there were no gestures or other input actions (such as "click") that could be mapped to the mouse. Because of these limitations, drawing and drafting programs using the mouse as the input device did not become popular until much later. But it was soon evident that a larger mouse ball was needed for use with larger mice. One of the first mice that could be used with larger balls was the high-quality Smith Mouse. In 1984, the Tracing-Plotter Tool Box, and the Steering Wheel tool

External systems External systems are AutoCAD components that are not produced by Autodesk, but that have been developed to function as part of the AutoCAD products. Autodesk ActiveMedia allows importing and exporting .dwg, .eps, .icm, .ifd, .ipf, .jpg and .pdf files directly to a web-browser or other client. Autodesk also supports ActiveX controls, which is similar to the Visual LISP, but has more development options. ActiveX controls are very similar to Microsoft COM based controls and were deprecated with the release of AutoCAD 2005. Command-line interface AutoCAD supports the option to execute or control commands through the command-line interface (CLI). The command-line interface runs AutoLISP scripts through the command line interface. The CLI is a standard command line interface provided with the software, similar to the one in Microsoft Windows. The CLI is initiated from the command line menu on the menu bar. The command line interface supports both Command Scripts and User Forms. Commands have arguments, which can

be entered in the format of "string[integer]", where integer is a number or letter that corresponds to a command. For example, the command move (3,25), (1,2), (100,1) can be executed by entering "move(3,25),(1,2),(100,1)" in the command line interface. The AutoLISP function that can be used to execute a command is dotcommand(), which takes a string with the command as an argument and returns 1, 0 or -1 depending on the result. When executed as a script, AutoLISP script can return 0, 1, or -1 depending on the input arguments and previous setting of variables. A command can be called from the command line interface. The command string with command name and arguments must be concatenated together. The execution of command is defined by the scope, which is a list of variables needed for the command to run. The variables are separated by commas. For example, the command mov(Z, 1,1),(X,1,2),(Y,2,2) can be executed by execute "mov(Z, 1,1),(X,1,2),(Y,2,2)"
